

142. Linked List Cycle II

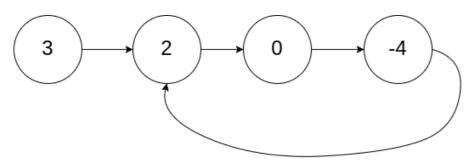

Medium ☐ 5527 ☐ 375 ♡ Add to List ☐ Share

Given the head of a linked list, return the node where the cycle begins. If there is no cycle, return null.

There is a cycle in a linked list if there is some node in the list that can be reached again by continuously following the <code>next</code> pointer. Internally, <code>pos</code> is used to denote the index of the node that tail's <code>next</code> pointer is connected to (**0-indexed**). It is <code>-1</code> if there is no cycle. **Note that** <code>pos</code> is not passed as a parameter.

Do not modify the linked list.

Example 1:

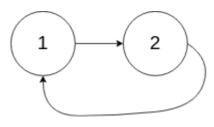

Input: head = [3,2,0,-4], pos = 1

Output: tail connects to node index 1

Explanation: There is a cycle in the linked list, where tail connects to the second

node.

Example 2:

Input: head = [1,2], pos = 0

Output: tail connects to node index 0

Explanation: There is a cycle in the linked list, where tail connects to the first

node.

Example 3:
